An Approach to Analysis the Reusability of the Object Oriented Software

Ashi Jain*, Anushree Asodiya, Deepak Agrawal
Computer Science & Engg, AITR Indore, India

Abstract

Reusability Metric is used to provide direction to increase productivity and maintainability of the developing application. One must search for good tested software component and reusable. Some of the developed software can be useful for the other developer also. In this manner, it is proving that code specifics to application requirements can be also reused in develop projects related with same requirements. The idea of this research work is to suggest an approach for reusable component. A process that takes source code as an input that will help to take the approximately judgement which reusable artefacts particular software should be reused or not.

Keywords: software reuse, reusability, metrics, CK metrics, cyclomatic complexity

Introduction

In today’s era, everyone is interested to increase the productivity, and reducing the cost of products that we are developing, and provide better quality in the software. There are various types of quality attributes available from which one can be identify the software quality. Reusability is approach that not only increases the productivity but decreases the maintainability of the software, which is to reusable the existing component. Because, time and effort already spented for the developing product. The earlier software modules were already well tested and designed. We should reuse earlier software.

Skill may help us not only to learn how to build reusable components but also to identify reusable components among the wealth of existing programs. Existing programs contain the knowledge and experience gained from working in the particular application domain and meeting the organization’s software needs. If we could extract this information efficiently, we could gain a valuable resource upon which to build future applications. Reusability save the lot of time for developing the software and also reduced the cost of the software development. It is also increases the software performance. Objective of the any system organization is to provide the good quality product and reduced the cost for the same.

Reusability

Reusability measurement is allowing for identify the reusable modules from being program and way to build. Some Department and Organization, along the increasing level of software reuse, development cost taken to develop the software and save the cost and time. Department of U.S. saved 300 million $ by increasing the 1% reusability software. Being software programs contain the knowledge’s and experiences of the developers who are good in particular application domain area. So we take out information from being program which comfort to require of the software system then it is beneficial for the organization.

There are many examples where reusability helps

a. In Missile Systems Division (MSD) using the computer software reuse concept it increased the 50% productivity.

b. American Navy utilizes the reusable modules which reduce 26 % of labour required to develop and maintain the Restructured Naval Tactical Data Systems (RNTDS).

c. Magnavox saw when we are using the reusable modules to develop the Force Fusion System Prototype (FFSP); it reduces the 20% of the development time of estimated time for developing the new system.

We determined from requirement stage to last stage of the software development .In Software development life cycle Reuse concept is not determined to only coding stage. These are several phases where software development is reused:

a. Code
b. Requirement
c. Architecture/design documentation
d. Test plans
e. Specifications
f. Design
g. Manuals
h. Templates
i. Design decisions.

Previous work

Michael a cusumano suggested that reusability also needs to be seen as a administrative and organizational problem. In this paper, the discussion was especially on techniques and tools used for the development of quality software’s. Which in the mid-1980s was regularly delivering software systems with nearly 50% reused code. Finally, the paper concluded that Reusability, and the promising reuses approaches, actually fell across a range.

Young Lee suggested a proposed quality model for object oriented software called as Reconfigurable Automated Metrics for Object (RAMOOS). The quality model points the maintainability and reusability aspects of software which can be successfully predicted from the source code. The modal works during the time period of software development.

James M.biemen suggested that derivation for the measurement of software reuse and introduces some definition, attributes and abstractions. In this paper the focus is upon the importance of the standpoint of the observer when analyzing, measuring and profiling reuse using measurement theory. The author has given measurement theory for measuring the concept of reusability. He also compares the measurement theory with the traditional object oriented approach.

Dandashi F. Suggested that how productivity and maintainability play an important role in software quality assurance. the author tried to develop some sample application using some technology and try to find a way that help to enhance the productivity of the software.

Selby providing the approach which supporting the modification of reused code Selby classifying the module into a particular category based on the percentage of reused Code is modified in make new module. These categories are:

a. Complete new module.
b. Reused Module with grater then equal to 25 percentage changes.
c. Reused Module with less than equal to 25 percentage change.
d. Module that are reused without change.

All these measurement are based on only one Attributes program size or program length. Selby add one another attributes modification. Reuse Measure Derivation As indicated in the title, this paper gave a description of how to derive measures of software reuse in object oriented systems. The method used to derive measures of software reuse, is derived from measurement theory and was described as.

a. Define considerable and identify and nonrational, realized attributes of software reusability, we must qualitatively understand what we want to evaluate.
b. Determine precisely the attributes to be measured and the documents. The measurement must be able to specify and indications of the measurement and the aim with higher precision.
c. Development of formal methods with higher level of abstractions which describe the attributes. Formal designs for definition to produce quantitative evaluate to study these abstractions without any ambiguity in them.
d. Devising the relationship of the model with the attributes with this quantitative measurement. These relationships must be in consistency with the specification of attributes and quantitative values.

Assessing Module Reusability:

In these paper Propose the Conceptual model for estimating the reuse of the module. Reusability determines the reusability of the module as product of its applicability and functionality. In this paper define model of Reuse as function of Applicability and Functionality.

Functionality:

Functionality of the module is determined as number of situation in which this module is Use, based on the specification. Important Problems will get a high functionality, while a module that covers a few specific, rare problems will get a low functionality.

Applicability:

Applicability measuring the number of situations in which a module can be reused. When the module can only be applied in 50%of the situations where its specified features are needed, then its applicability is 50%. The applicability of a module is 100% when any situation that calls for features provided by the module, the module can actually be used. There are many reasons why a module's applicability might be less than 100%, including:

a. Technical limitations, such as programming languages and platforms.
b. Incompatibilities by details of the interface. 
c. Incompatibilities by external dependencies. 
d. Architectural mismatches.

Definition of reuses types

Bieman et al’s [6] determined the various types of reuse and defined the three types of reuse in the three perspectives. These are explained as follows:

a. Public Reuse:
Fenton define the public reuses as “the proportion of a product which was constructed externally”.

\[
\text{Public reuse} = \frac{\text{length (E)}}{\text{length (P)}};
\]

E is the code developed externally.

P is the new system including E.

**b. Private Reuse:**

Fenton defines private reuse (or possibly more appropriately internal reuse) as the “degree to which modules between products are reused within the same product”.

Fenton uses the call graph which represents the flow connection of the module. In these graphs node represents the module and they are connected through edges. If one node calls another node then edge displays the connection between them. Fenton provides the formula for calculating the private reuse in call graph as follows

\[
R(G) = e - n + 1;
\]

e is total no of edges in graph. And n is the number of the nodes in graph.

**c. Leveraged Reuse:**

In Leveraged reuse means modifications of reuse is allowed.

**d. Direct Reuse:**

Direct reuse is reuse without using the intermediate entity. One module directly calls another module.

**e. Verbatim Reuse:**

In Verbatim reuse means modifications of reuse is not allowed.

**f. Indirect Reuse:**

Indirect reuse is reuse through an intermediate entity. When first module calls second module and second module calls the third module then first module indirectly calls the third module.

**Three Perspectives for Reuse:**

Bieman provided the three perspective view for identifying the reuse views. These are described as follows:

**a. Server Perspective:** perspective of the library component known as a server perspective. Server reuse of the any class will characterize how one class is using the other class.

**b. Client Perspective:** Client perspective means how one particular entity is using the other entity i.e. how the new system using the existing system.

**c. System Perspective:** it is the combination of the both server perspective and client perspective.

**Properties of software which affect reusability**

There are some software attributes which affect the reuse. The relationship between these attribute and the reusability are explained as follows:

**a. Complexity:** when the complexity of the class is high or for developing the class developer uses a complicated structure then that type of class is difficult to reuse and difficult to understand.

**b. Complexity of interface:** Complicated interface make reuse difficult.

**c. Class size:** when the size of the class is large then it is difficult to understand and difficult to reuse.

**d. Dependencies:** Dependency of the single module to various modules may also make reuse more difficult.

Reusability is depending about the, adaptability, portability, maintainability reliability and understandability. We are dealing with the java program that way portability is not issue for us. Complexity is of two types’ structure complexity and inheritance complexity. And we are treating with static code therefore we are not considering the reliability an affect which is the reusability, since reliability is measure in terms of the average time and error which is measured, on the execution of the program. Understandability is depending on the structure complexity, documentation level of the programs and size.
function do describe in the starting of the purpose. Understandability is also depending along the size of the module. When the size of the module is high, then it is difficult to understand. If the Complexity of the module is high then module is difficult to understand. We tell module is more complex when module holds more composite data structure in his program and more decision statement Complexity is two types beginning is structure complexity it was easily measure along WMC metrics and second is inheritance complexity; this complexity is measurement by using the DIT and NOC metrics. When the program is using the concept of inheritance, then these metrics are used for measuring the inheritance complexity.

![Diagram showing factors and metrics in which Understandability depends](image)

**Fig 2 Factor and Metrics in which Understandability depends**

- **a. Lines of Code (LOC):** This metrics applied for measuring the size of the program by considering the no of lines in program. Lines of Code (LOC) counts all lines like as source line and the number of statements, the number of comment lines and the number of blank lines.

- **b. Comment Percentage (CP):** CP is computed by number of comment line separated along Line of Code. High evaluate of the CP increases the maintainability and understandability.

\[
CP = \frac{Comment\ Line}{LOC};
\]

- **c. Weighted Method per Class (WMC):** This metrics is applied towards calculating the structure complexity of the programs. Method complexity is measured by using Cyclomatic Complexity and WMC is sum of complexity of the all methods which is applied in class. Suppose class is getting the methods (m1, m2, and m3...mn) and complexity of the methods are (c1, c2, and c3...cn) then

\[
WMC = c_1 + c_2 + c_3 + ... + cn;
\]

Cyclomatic Complexity causes foundation of the graph theory and is computed in one of the 3 directions. Number of regions in flow graph. Cyclomatic Complexity determined in flow graph as follow

\[
C(G) = E - N + 2;
\]

Where N is the no of the nodes in graph and E is the no of the edge in the graph.

Cyclomatic Complexity defined in flow graph as follow

\[
C(G) = P + 1;
\]

Where 'P' is number of predicate nodes in the graph. Statement where we are taking some decision are called predicate node.

- **d. Depth of Inheritance Tree (DIT):** This metric is applied for measuring the inheritance complexity for the programs, when programmer usages the inheritance in his program then this Metric can be utilized. DIT is the Maximum depth from the root node of tree to special node. Here class is represented as a node. Deeper node in the tree accepts more no of the methods because they inherit the more classes in the tree and it make the class more complex.

- **e. Number of Children (NOC):** NOC is applied when there are many numbers of the Sub-Classes of the Particular class in hierarchy of the class exist. When children of a class are more then it requires more testing because super class may be misused.

- **f. Public Interface Size:** Public interface size is determined when a number of the public method deliver in the class. Which describe how much other class is using that class’ method?

**B. Maintainability :**

The degree to which the system or module of the software can be modified easily in order to fix bugs, adding quality attributes or for adjustment of the operating environment change, increase efficiency of the system. Maintainability depends on the following factor, modularity these are size, complexity. We say module is more complex if module comprises more decision statement and more complex data structure in his program. When the Complexity of the module is high then module is difficult to maintain. Modularity is measure by using the coupling metrics and cohesion metrics and Maintainability heavily depends on the modularity. Modularity is idea for managing the complexity of complex system by dividing it into various small modules and this module is communicates by using interface. We handle the complexity by using the concept of the modularity. By using the concept of modularity we find clear and simple system. When the module is high cohesive then it is easy to maintain. If module having the more no of the local method then it difficult to maintain. And if size of the module is high then it difficult to maintain if the coupling of...
any module with other module is low then this module is easily modified and easy to maintain. Maintainability is also depending on the cohesiveness of the module. If we write code for any module and interested in measuring the quality of module then the best criteria for measuring the quality of the code is measure based on quality factor maintainability. Maintainable code is more flexible, code is not maintainable because module performing several functionality and invoking other module. Any module is more maintainable if we add easily new functionality and exchange existing functionality of the module. Metrics victimized for calculating maintainability of the program, Shown in the Figure 3.

**Figure 3 Factor and Metrics in which Maintainability depends**

**C. Adaptability:**
Adaptability determines as how easily software satisfies requirement or and user requires of the new environments from being system and system constraints. Now suddenly business environment or business require is changed, thus handling this situation adaptability is one of the important component or weapon. Business market situation is change frequently so our software system should be adaptable to satisfy this requirement. It doesn’t intend whatever software. We build up from oop is always adaptable. In object oriented concept applying the ability to build adaptable software. When the coupling of module is low and cohesion is high that signifies module is easily adjust in new environment from old environment. For make adaptable module we concentration on cohesion and coupling of the module. Metrics used for calculating adaptability of the program, Shown in the Figure 4.

**Figure 4 Factor and Metrics on which Adaptability depends**

**Approach for identification of reusable module**

a. **Extract the source code:** In this phase we analyzed the source code and extract useful information and store it in memory, which is necessary for calculating the all metrics, these metrics are necessary for evaluate factor on which reusability depend.

b. **Calculating the Metrics:** In this phase we calculate, all metrics which describes in above section, for implementing these metrics, we used information gathering from extract phase. And result of the all metrics is store in memory. All metrics are concern with object oriented system.

c. **Display:** In this phase we calculate the reusability of the source code. We give the some weighted to each metrics and finally we determine the reusability of the sources code. And display source code is reusable or not.

**Figure 5 Steps follow for identified reusable module**
Conclusion
The purpose of this paper is to find the approach and way to calculate reusability of object-oriented programs. Reusability is one of the quality attributes and it is of prime importance in object-oriented software development as reusability leads to increase in developer productivity, reduce development cost as well as reduce time to market. The work presented in this paper can be effectively used to calculate the reusability of any object-oriented software module.
