Abstract
Plastic are certainly most versatile of all known materials today and have therefore, established themselves in enviable position from where are not even possible to replaced. Injection molding machine is one of the most widely used method of conversion of plastic into various end products application to wide range of plastic materials from plastic commodity to specialty engineering plastic. In injection molding machine stationary platen play a very important role. During the process generally compressive stress generates at particular regions. As load varies with fast rate there is chance to failure of tie bar rod. Due to heavy mould shape, size of platen also change, that’s increase its weight as well as stress level at certain region and this is not good in practice. This leads to failure of platen or failure of tie rod due to stretching by nut and platen. This create loss of money (Production stop), man (injured due to accident), and material (increase inventory cost). The aim of this project is study about those areas where stress can affect the failure of tie bar due to heavy weight of stationary platen the deflection or misalignment with movable platen. Finally redistribution of stress so that uniforme stress achieve (optimization of platen). This project is including Finite Element Analysis and Design Optimization of a Typical Structural Component of a Plastic Injection Molding Machine. The aim of project is to optimize a typical structural component (stationary platen) by using finite element analysis after checking induced stresses with allowable design stress. Hence design modification of platen is carried out to achieve good strength and cost effectiveness.

Keywords: FEA, Molding machine, Stationary platen, Optimization.

Introduction
An injection molding machine can be defined as a machine that produces formed objects in a discontinuous manner primarily from macromolecular materials.

➢ The forming is a primary forming under pressure.
➢ Part of plasticized material in the machine is injected through a channel in to mold cavity.
➢ Injection molding machines are Composed of three parts:
(1) The injection unit,
Which feeds Plastic melt to a
(2) Mold,
This is held closed by
(3) Clamping unit.
➢ The pressure inside the mold cavity generates a mold opening force which is transferred through shear and compressive stresses to the Centre of the machine platens.
➢ The platens then transfer the load through shear stresses to the tie bar retainers.
➢ The retainers, in turn, transfer the load through shear stresses to the tie bars, which should be in pure tension. It should be noted that the mold’s guide bushings and the machine tie bars are also subjected to possible lateral loadings.
➢ This machine design has theoretical minimum number of 20 structural components with 8 axial or compressive stresses and 22 shear stresses.

Methodology
Simplified FE Model

Fig 2.1. Simplified FE Model
Quarter Part of Simplified FE Model
- Using Symmetry of Simplified FE model
- So it is converted into quarter part.

Fig. 2.3. Quarter part of FE model with Nozzle and T-slot

Forces Applied On Stationary Platen

Fig. 2.4. Pressure Applied at Projected Area (Back View)

Data Reduction
- A = 1340 mm
- B = 1140 mm
- X = A – Strain rod diameter
  = 1340 – 190
  = 1150 mm
- Y = B – Strain rod diameter
  = 1140 – 190
  = 950 mm
- Force applied = 775 tonne
  = 775*1000 kg
  = 775*1000*9.81 N
  = 7602750 N
- Pressure applied in the projected-rectangular area = 1.565 kg/mm²
  = 1.565*9.81 N
  = 15.35 N
- Force applied due to Each Strain Rod = Force / 4
  = 7602750 / 4 N
  = 1900687.5 N
- Maximum bending stress (σ) = 35.68 N/mm²
- The stress concentration K₁ and K₂ are constants.
- Volume = 1.9863855e+08 mm³
- Surface area = 4.6468334e+06 mm²
- Density = 7.1000000e-09 tonne per mm³
- Mass = 1.4103337e+00 Tonne.
Design Optimization
Design Modification for Optimization

Fig 3.1. Iteration (1) Mass Reduced = 109.28 Kg

Fig 3.2. Iteration (2) Mass Reduced = 282.52 kg

Fig 3.3. Iteration (3) Mass Reduced = 227.04 kg

Fig 3.4. Iteration (4) Mass Reduced = 95 kg

Fig 3.5. Iteration (5) Mass Reduced = 460.6 Kg

Fig 3.6. Final optimized Iteration (6) Mass reduced = 275.52 Kg
Justifications for each Iteration

- There are much other iteration carried out for design optimization but we are showing final six iteration which gives the best result.
- Maximum stress developed at nozzle slot because nozzle slot acts as a stress raiser.
- The stress concentration factor is very high at nozzle slot.
- There are following iteration carried out for optimization of stationary platen
- In Iteration (1):- By providing fillet at Nozzle slot for reducing stress concentration.
- In Iteration (2):- By providing boss at upper side of Nozzle slot for minimizing stress concentration.
- In Iteration (3) & (4) :- By providing fillet and Revolve cut at Nozzle slot and try to convert Nozzle section in to circular or elliptical shape in this way stress concentration can be minimize.
- In Iteration (5) :- Further applying bigger radius revolve cut and fillet at Nozzle slot In this way try to reduce stress produce at Nozzle slot.
- Iteration (6):- Keep the revolve cut and fillet same as the iteration (5). But add more material added by applying fillet at pockets. Due to this the stresses and deflection values can be minimized at satisfactory level. It is considered final optimized stationary platen.
- Iteration (6) gives following stress, Deflection and weight reduction.
  - 1\textsuperscript{st} principal stress (minimum mold case) = 99.073 N / mm2
    - Deflection = 0.5254 mm
  - 1\textsuperscript{st} principal stress (Vertical mold case) = 105.13 N / mm2
    - Deflection = 0.4926 mm
  - 1\textsuperscript{st} principal stress (horizontal mold case) = 68.66 N / mm2
    - Deflection = 0.4570 mm
  - Weight reduction = 275.52 Kg.

Analysis of Optimized Stationary Platen

- Volume = 1.8893679e+08 mm\(^3\)
- Surface area = 3.9688364e+06 mm\(^2\)
- Density = 7.100000e-09 tonne / mm\(^3\)
- Mass = 1.3414512e+00 tonne

Result
- 68.88 \times 4 = 275.52 Kg Mass reduced
- Percentage of weight reduction\(= 5\%\)
Fig 3.9. Third principal Stress (Minimum Mold Case)

Fig 3.10. First principal Stress (Vertical Mold Case)

Fig 3.11. Third principal Stress (Vertical Mold Case)

Fig 3.12. First principal Stress (Horizontal Mold Case)

Fig 3.13. Third principal Stress (Horizontal Mold Case)

Fig 3.14. Horizontal relative Deflection for Minimum load case

Results Validation of Optimized Platen

Final Optimization Results

- 1st principal stress (minimum mold case) = 99.073 N / mm$^2$
  Deflection = 0.5254 mm.
- 1st principal stress (Vertical mold case) = 105.13 N / mm$^2$
  Deflection = 0.4926 mm.
- 1st principal stress (horizontal mold case) = 68.66 N / mm$^2$
  Deflection = 0.4570 mm.
- Allowable stress: $\sigma_u \times K3 = S1$ N / mm$^2$, Where $K3$ = constant.
- So above all induced stresses are less than the allowable stress.
- All the stresses are coming under the design stress, and deflections are under the limit.
- Then results are correct.
- The Deflection Values are within limit.
- The relative deflection for horizontal and vertical are also within the limit.

Conclusion

- Casting and Machining Models of existing stationary platen has been created by using Pro/E creo.
- FE analysis of existing stationary platen is carried out by using ANSYS software.
- T-slot and Nozzle slot have been included in the existing platen and FE analysis has performed for the existing stationary platen to incorporate with T slot and Nozzle slot.
