ABSTRACT

The use of the biocide as a disinfectant for use in magnetic resonance rooms represents a technological challenge concerning the application of neutral electrolyzed oxidizing water (NEOW). Using a prototype OPTI-JET CS MD1 MR in magnetic resonance rooms were performed appropriate use of aerosolisation and precise dosing of NEOW. Thus, we refute the problem to disinfect apparatus 3T energy. Disinfectants of choice are therefore expected to possess properties such as rapid, residue-free action without any damaging effect on the sensitive electronic equipment. This paper discusses the use of the NEOW as a biocide for the disinfection of diagnostic rooms and equipment.

Material and methods: We produced and used OPTI-JET CS MD1 MR aerosolisator whereby was performed aerosolization. The presence of microorganisms before and after the aerosolisation was recorded with the help of cyclone air sampling. Colony formed units (CFU) was counted.

Results and Discussion: The number of microorganisms in magnetic resonance 3T room was low as expected. Nevertheless, a possible CFU reduction of 87% was recorded.

Conclusions: The research has shown that the use of EOW for the air and hard surface disinfection can considerably reduce the presence of microorganisms and consequently the possibility of hospital infections. It has also demonstrated that the use of OPTI-JET CS MD1MR is very good.

KEYWORDS: Biocide, electrolyzed oxidizing water (EOW), disinfection, microorganisms, OPTI-JET CS MD1MR

INTRODUCTION

The number of inspections and interventions on patients is increasing, while the time required for the disinfection of surfaces, premises and equipment is shortened. With larger microbial loads of surfaces and patients as well as medical personnel are increasingly exposed to microbial contamination, especially by-resistant strains of microorganisms. In doing so, highlighted diagnostic procedures in modern electronic equipment, which is difficult to quickly and successfully disinfected [2, 3, 4, 10, 14, 22]. The market does not offer an adequate, reliable, rapid and safe disinfection process 3T magnetic resonance devices. The main factor of successful disinfection is time itself. Selection of a suitable disinfectant is largely dependent on the overall process of disinfection procedure. It basically has a disinfectant reflect the speed of effect and free radicals on the surfaces. On the market, the are more than 250 substances having a biological effect which cause disinfection. On the bigger problem we encounter when we want to use such assets on surfaces in hospitals for hospital-acquired infections such as MRSA (methicillin-resistant staphilococuc aureus) and other infections [13, 23, 30, 45, 11, 38, 5, 1, 21, 16]. Patient couches of computer tomography (CT) and magnetic resonance imaging (MRI) scanners are very hard to access when it comes to cleaning and disinfection [11; 30; 38]. Consequently, new approaches to disinfection procedures have been studied. Thanks to its mechanism of action, neutral electrolyzed oxidizing water (NEOW) has been considered as a possible biocide of the new generation [36, 37,44, 32, 42]. The principle of the NEOW production has been known for some time now. Basically, the alkaline ionized water and acid oxidized ionized water are generated from diluted non-iodised cooking salt (NaCl solution),
whereby the alkaline fraction reaches a pH of 11–12, while the acid one has a pH of 1–3. While the alkaline ionized water is considered to have a cleaning effect, the acid one has extremely biocidal effect. Mostly, the effect of the EOW action has been attributed to the pH change only. However, more detailed analysis has revealed that electro-oxidized water works through several mechanisms. Most patients with serious infections typically have some type of imaging procedure performed during the course of their treatment. Radiology departments and outpatient imaging centers must take appropriate action to assure patients that their MRI scanner is not a significant hub for microorganisms capable of causing infectious diseases. However, for a multitude of reasons, MRI suites often lack the most basic of safeguards against infection, where, due to its unique environment, it is extremely difficult to implement and maintain an effective infection control policy. Because of the dangers from extremely strong magnetic fields [12], as demonstrated by a well-publicized patient death from an accident in an MRI [19, 20], housekeeping staff and most cleaning equipment are usually prohibited from entering the MRI suite. The resultant lack of thorough cleaning was clearly demonstrated in a recent study from Ireland that cultured MRSA from within the bore of the MRI system [41]. MRSA was originally identified in 1961 and is now widespread throughout healthcare facilities, both hospital and outpatient settings [42]. The most common source for transmission of MRSA is by direct or indirect contact with people who have MRSA infections or are asymptomatic carriers. In 1972 MRSA accounted for only 2% of all Staphylococcus aureus infections, but now it is responsible for 50 to 70% of these infections [42]. MRSA is among those microorganisms commonly referred to as a “super bug”. MRSA may be community associated, CAMRSA, or healthcare associated HA-MRSA [25]. The morbidity and mortality of these bacteria is staggering. On average, hospitalizations for the treatment of MRSA versus other infections have a length of stay approximately 3 times longer and are 3 times more expensive [29]. Additionally the risk of death is 3 to 5 times greater for patients infected with MRSA versus methicillin sensitive Staphylococcus aureus [29, 44]. A major concern for imaging centers is that MRSA can be carried by asymptomatic persons. Worldwide, it is estimated that up to 53 million people are asymptomatic carriers of MRSA [35, 40]; of these it is estimated that 2.5 million reside in the United States. Approximately 1% of the US population is colonized with MRSA [43]. Both infected and colonized patients contaminate their environment with the same relative frequency [43]. Therefore, any patient lying on an imaging table could be a carrier capable of contaminating surfaces in the radiology suite. MRSA and other pathogens can live on inanimate surfaces including common table pads and positioners for periods as long as several months [18, 24, 7]. The MRI Suite The area of greatest challenge for preventing the transmission of MRSA and other infections in Radiology is clearly the MRI suite. Due to the high magnetic field, posing a danger to both the personnel and to damaging the MRI itself, and to comply with the American College of Radiology recommendations [7] it is the author’s experience, that many free standing imaging centers and hospitals do not allow cleaning crews to enter the MRI suite. Therefore these MRI suites are rarely, if ever properly cleaned. This is a risk to staff and patients because MRSA can be transmitted by contact with contaminated surfaces such as mattress pads [7, 8]. It has been proven that MRSA can survive on surfaces such as tabletops and charts for up to 11-12 days [27]. Similarly, Vancomycin-resistant enterococci (VRE) had a 50% survival at seven days on upholstery, furniture and wall coverings and could easily be transferred by touching contaminated surfaces [33]. There is an increased risk of VRE/MRSA for patients in the presence of environmental contamination, 5.1% increased risk for MRSA and 6.8% for VRE [35, 26]. There is an increased risk of an MRSA acquired infection for patients admitted to a room that was previously occupied by a patient colonized with MRSA [26]. At many MRI centers, there exists a false belief that merely placing a clean sheet over the table pads, without actually cleaning them between patients, will prevent the spread of infectious agents. What is most concerning is that very few MRI centers clean their pads even once a day, much less between patients. Cleaning pads during working hours typically has a very low priority, because it is time consuming, decreases throughput and thereby decreases the center’s productivity and negatively impacts the financial well being of the center. Additionally, MRI technologists, especially those who trained in the 1970’s and 1980’s, had little training in infection control or proper cleaning procedures. An average MRI may scan 3,000 to 5,000 patients a year. CT scanners usually scan double or triple that number. The probability is that at least 50 – 100 of these patients are infected with MRSA or other HAIs [15], and many more are carriers. Another area of potential exposure to infectious agents is the use of IV contrast material for both CT and MRI, which significantly increases the risk of blood contamination. The simple task of removing a needle from a patient’s arm and placing it into the sharps container has great risk. Blood can drip from the needle or from the puncture wound onto the pads, table and floor. This blood can often be unnoticed by a busy technologist or doctor performing the injection resulting in a contamination risk. It is not uncommon to find dried blood in an imaging suite which is an excellent culture medium for MRSA. There is also concern for spreading infectious bacteria by direct or indirect contact among the imaging staff and patients within the imaging department or center. MRSA infections can be acquired by staff members through a simple cut or other break in the skin that may not be noticed during a busy day. Therefore, hand-washing between patients as well as hand
sanitizer use for the entire staff is of crucial importance [9, 17, 29]. Regarding mobile MRI, ensuring proper hygiene is even more difficult since they do not have a sink or running water.

MATERIALS AND METHODS
In research (the possibility of using neutral electrolyzing oxidizing water - NEOW) carried out in 2012 at University Medical centre Maribor Department for Radiology we come to the important positions that indicate the potential for rapid and reliable disinfection without delays on surfaces. Depending on the specific environment in the operation of the device MRI, we consider to introduce, customize and upgrade with the corresponding modified equipment that can be used in an environment with a 3T magnetic resonance energy allowing it to run. For this purpose we have developed aerosoliser OPTI-JET CSC MD1MR with special nozzles for cold fogging, which are compatible with 3T energy. The aerosoliser we will set up as part of the device software 3T magnetic resonance taking into account the manufacturer's instructions for magnetic resonance. With the help of the air sampling method we will be tested reliability of the process cold fogging, including air and surfaces disinfection. By placing of OPTI-JET CSC MD1MR aerosoliser will facilitate the smooth application NEOW in the space of the magnetic resonance device. At regular aerosolisation we sampled air and surfaces in magnetic resonance once a month or if necessary several times. By means of taking samples in the area, we will test the reliability of the procedures NEOW cold fogging, which allows for the disinfection of surfaces including air disinfection. To examine the effectiveness of disinfection of air will make a cyclonic air sampling. The importance of cold fog and the possibility of practical application of the modified model OPTI-JET CS MD1MR is that the aerosoliser is all the time located inside of the magnetic resonance suite. To determine the effectiveness of disinfection of air to be performed cyclonic air sampling. However you can use it if necessary without any loss of time. Cold fogging is shown as the method of choice, because this once obscure disinfect and reach the tunnel surface of apparatus, appliances and room air of magnetic resonance. In its search for a possible solution, the Radiology Department of the Maribor University Medical Centre (UKC) decided to test the air samples and the samples taken from the test surfaces of the various types of diagnostic equipment in order to establish the actual condition and the scope of the micro-organism presence in the air and their significance for the surface contamination. Additionally, the possibility of the air aerosolisation with the NEOW was tested. More specifically, the product tested was NEOW Steriplant® N produced by OBISAN – Institute for Biotechnological Research and Development from Murska Sobota, Slovenia. The available commercial form of the product contains sodium hypochlorite, chlorate, chlorine dioxide and ozone. Its pH value ranges between 6 and 8 and its redox potential is +800 ± 100mV. The research involved MRI 3T room. The purpose of the research was to establish the efficacy of the applied EOW biocidal action on the present bioaerosol. The identification of the micro-organism presence in the air and on surfaces was carried out to establish the level of the contamination in order to be able to determine the importance of the reduction of the micro-organisms present in the air with the NEOW aerosolisation. For air sample collection method we used Coriolis Air Sampler (produced by Coriolis, France) using cyclone technology. Through the whirling motion of the medium and with the help of the centrifugal force, the samples were collected to a bioaerosol and prepared for further treatment. With the air flow rate of 300 litres per minute, altogether 1,200 litres of air were pulled through the liquid collection media during the collection time of 4 minutes. As a liquid medium, the sterile physiological saline was used in which the bioaerosol from the air was collected. All collected samples were taken while the air ventilation system and 3T system was on and they were transported to laboratory for further treatment at the temperature of 4°C. Following the expiry of that time, the grown colonies were counted (ISO 132697/2002). Air samples collected in the suspension of the physiological saline were first diluted and then sown to a medium. Depending on the cultures grown, further determination was carried out (ISO 4833/2003). What followed was the counting of micro-organisms and the determination of their actual total number.

RESULTS AND DISCUSSION
After we have done air sampling in the diagnostic rooms of the Radiology Department of the Maribor University Medical Centre (UKC) we can conclude the following. As anticipated, the number of microorganisms present in the diagnostic room air was low because of good cleaning workflow. Clearly, to get a more reliable confirmation of the decrease in the number of microorganisms it is preferable – from the point of view of the aerosol biocidal action efficiency – to ensure as high initial number of microorganisms as possible. However, this research was determining the reliability of action in actual conditions. As a result, the recorded decreases were smaller than they might have been in experimental conditions. The air condition ws all the time on between air aerosolization and the sampling method. The samples were analyzed by the method of ISO 132697/2002 and ISO 4833/2003. The results are presented in the following table 1. Wee count the number of colony formed units (CFU) in m³.
We note that aerosolisation was reduce the presence of microorganisms in the air of 87% but concentration increases over the time because of the working air conditioning system. We believe that the use of the biocide aerosol Steriplant® N in practical terms in prepared space in which substantially reduce the burden of microorganisms. We believe that this helps to establish a bio-security between operational and diagnostic interventions. Considering the fact that the biocide aerosolization need 6 – 8 ml of biocide solution /m³ of air can reach very small amounts of disinfectant effects in operation rooms and equipment. Important features of the biocide Steriplant® N hospital environment is a based on the research data gathered, one can conclude that there is a constant presence of microorganisms in all diagnostic rooms, which is most likely a result of the air condition room ventilation that is based upon forced overpressure system. The use of Steriplant® N proved to be efficient and safe in all applied ways. Also, no eventual damage to exposed devices or staff was recorded. The results have shown that the diagnostic room aerosolisation reduced the total number of microorganisms 87%. During the counting of CFU units was observed also some suspicious colonies which were subject to further determination. However, in none of the cases studied were there discovered any particularly dangerous agents to health.

CONCLUSION

Patient safety should be the primary concern of any healthcare organization. Protecting patients and staff takes a concerted effort by all the parties involved in diagnostic imaging. There is no question that infection control has not received the attention it deserves. There is a growing concern that at least some of the spread of infectious agents could be coming from outpatient imaging centers and radiology departments in hospitals. However, almost no attention has been paid to infection control inside these MRIs. This is demonstrated by the fact that there has been only one published research project ever to even explore the possibility of infectious disease inside an MRI and this study was performed in Ireland and presented in 2006. The study only tested one magnet, but found that there was MRSA present in the magnet. It is quite telling that there have been no follow up studies since that time. Further research is now required to determine the percentage of MRIs in this country that harbor MRSA. It is crucial that we assure patients that proper infection control procedures are being performed in the MRI suite to ensure the future success of MRI. It is understandable that this would be somewhat painful and expensive for MRI centers and hospitals, however in the long run, it will be crucial to address this issue before it becomes a national problem requiring government intervention and regulations. Imaging centers and hospitals owe it to their patients, to assure that their safety is the top concern during their MRI experience. To conclude, the applied liquid proved to be an efficient disinfection agent. No unwanted effects on material means or people were recorded. Its application is recommended also from the economic point of view. While its applicability has certainly been proved, a further benchmark research comparing efficiency of Steriplant® N with the usual disinfecting agents used in the hospital would be advisable. The main advantage of NEOW compared to other biocides is in its broad spectrum of activity against microorganisms and in its universal applicability. It is resistance and residue-free requiring no surface washing, environment-friendly – it is ecotoxic and safe use (no protective equipment is needed). Surface application requires a solution of 6-8ml/m² only. In brief, there are numerous NEOW application possibilities which are mostly a result of its broad spectrum of activity, environmental friendliness, safe use, possible application in the presence of animals and residue-free application (no additional surface washing needed). All this represents an important advantage compared to all other biocide groups. Broad spectrum of activity mainly in the form of resistant microorganisms (metycillin resist with S. aureus, E. coli) uncorrosivity, security for operators disinfection, medical staff and patients, and that does not remain on the surfaces of the biocide residues (not required disposal of residues). We also wish to highlight the importance of the choice of the methodology air sampling for the presence of microorganisms.
